Haemophilus influenzae Invasive (Meningitis)

Transmission, Exclusion

Source: upper respiratory tract of humans

Transmission

- Person-to-person (via respiratory droplets)
- Direct contact with respiratory secretions
- Neonates: intrapartum aspiration of amniotic fluid

Carriers 40-80% of children

Incubation

3-4 days (2-10 d)

(usually unencapsulated)

Meningitis, Pneumonia, Febrile bacteremia, Epiglottitis Septic arthritis, Cellulitis, Otitis media, Pericarditis

Contagious until antimicrobial treatment

Exclude all children until 24 hrs. after antimicrobial treatment

Most common in children <5 years

Diagnosis

- •Pleomorphic gram-negative coccobacillus
- •6 typable (capsulated) strains (a-f), + unencapsulated strains.
- •Type b is most common cause

Lab Diagnosis

- Culture: primary diagnosis criterion
 - -positive for $\emph{H. influenzae}$ in CSF, blood, synovial fluid, pleural fluid, or middle ear aspirates on chocolate agar
- •Serotype: differentiate between unencapsulated and encapsulated strains. Identify type (a-f).
- •Antigen Detection: Latex agg. On Urine/serum
 False positive (recently vaccinated, fecal contamination)
 False negative: Do not exclude if negative latex

Clinical Case Definition

- Children <5 yrs.
- Sudden onset
- Vomiting
- Lethargy
- Bulging fontanella- infants
- Stiff neck/back

Probable: Clinically compatible case with detection of Hib

antigen in CSF Confirmed: Clinically compatible case that is laboratory confirmed

Send culture to State Lab

Treatment, Prophylaxis

Treatment

- •Cefotaxime or ceftriaxone
- •Meropenem or combination of ampicillin and chloramphenicol
- •Antimicrobial therapy for 10 days (or more) intravenously
- •Dextramethazone in infants to decrease risk of neurologic sequelae— given before/concurrent with first antimicrobial dose

Prophylaxis

- •<u>Rifampin</u> –eradicates Hib from pharynx in 95% of carriers, decreases risk of secondary illness
- •Dose: orally once a day for 4 days (20 mg/kg; maximum dose 600 mg)

Indications for Prophylaxis in Households In households with

- at least 1 contact younger than 48 months of age who is unimmunized or incompletely immunized against Hib, or 1 contact younger than 12 months who has not completed the primary HiB immunization series
- → Rifampin prophylaxis is recommended for all household contacts, irrespective of age.

Exception: All members of households with a fully immunized but immunocompromised child, regardless of age, → rifampin because of concern for ineffective immunization series

Indications for Prophylaxis in Daycare Centers

1-When 2 or more cases of invasive disease have occurred within 60 days and

Un-immunized or incompletely immunized children attend the child care facility,

- → Rifampin prophylaxis to all attendees and supervisory personnel is indicated.
- 2-Single case in daycare with unimmunized or incompletely immunized children: many experts recommend no prophylaxis.
- 3-Unimmunized or incompletely immunized children should complete recommended age-specific immunization schedule

Control

Droplet precautions

Immunization of all children: Dose at 2, 4, 6 mos. with booster at 12-15 mos.

Close contacts + prophylaxis: see above
